BACKGROUND OF THE INVENTION

Many households have large collections of many kinds of entertainment media (for example, CDs, videotapes, videodiscs, books), and other items too numerous to keep track of easily via the methods currently in use.

At present, a person with a large collection of, for instance, music recordings, when trying to determine whether or not a new purchase would duplicate a previous one, is obliged to depend on memory alone or on unwieldy paper information, such as bundles of index cards. It is currently possible to enter data into a personal computer, and to print it out as a list. But for large collections, the printed inventories would be cumbersome, as well as quickly becoming obsolete, necessitating a lot of nuisance and waste.

If an individual must remember, after coming home to a stationary computer, to painstakingly enter information about each item purchased, as is the case at present, it is much less likely that these records will actually be kept up to date.

This invention combines hardware items that are currently ubiquitous to achieve novel results that would serve needs which nothing extant currently addresses.

Computers are not new, nor are inventory-tracking systems of various kinds, including inventory-tracking software. Hand-held scanners are in use for inventory tracking and control in warehouses and large retail stores.

Some retail stores allow consumers to temporarily make use of a barcode scanner, in conjunction with a computer with a database of product information, most frequently in order to facilitate price checking. The concept of an individually owned, portable personal inventory management system is very different in its ramifications from previous utilization of these components.

A Boolean search of over 1500 patents revealed nothing comparable to this invention. Patents which deal with barcode readers in conjunction with inventories are all aimed at businesses. For example, patent number 5,939,695 (for a "Product identification system using hand-held customer assistant unit with a code reader") is designed to benefit retailers. None of the patents referred to equipment owned by an individual consumer, rather than a store or other corporate entity.

In recent months there has been a lot of discussion on the internet about ways to take advantage of a device called the CueCat, containing a barcode scanner, which is being given away by a company called Digital Convergence (401 Park Avenue South, New York, NY 10016). Several web sites have instructions and suggestions for modifying these devices from their original purpose. A few people mention turning the barcode scanner in the device to the purpose of reading barcode data of various kinds. However, the CueCat is very limited in processing capability, so it can not store much information. These are used while physically connected to a computer, taking advantage of the computer's processing power and memory storage.

Cross (A. T. Cross Company, Lincoln, Rhode Island) offers a variant of the CueCat device in a portable form. It resides inside a Cross pen, and can scan and retain a limited number of barcodes. It has no display. Someone with this device can load the saved information into a computer via a docking device. That is the extent of its capabilities, so it is of limited usefulness.

Another company to suggest alternative uses for CueCats is Readerware (P.O. Box 12325, San Francisco, CA 94112-0325). This company makes software which can be used in conjunction with various barcode readers and computers to compile databases of information and to catalogue an inventory of books. This software helps users search for barcode-encoded data on the internet.

A new version of Readerware's software is available for porting data to a Palm Pilot (Palm, Inc. 5470 Great America Pkwy Santa Clara, CA USA 95052), which is a portable data storage device with a digital display. By loading data to the Palm Pilot, a user is enabled to take a database, such as a want-list of desired books, on shopping

expeditions. However, the Palm Pilot is not equipped for intake of information other than by coupling with a computer or via hand data entry, and lacks the software to decrypt barcode data on its own. Nor can it do the data-base comparisons to tell a shopper whether or not an item already is in "owned" inventory.

These recent technological developments appear to be leading toward the eventual development of a cohesive system such as the present invention, but none of them takes into account all of the needs that this invention addresses in one integrated package. All of them have significant gaps. Therefore, it would seem that the present invention is not an obvious use of the technologies it brings together.

BRIEF SUMMARY OF THE INVENTION

The invention is a method for keeping track of whatever items a user wishes to have catalogued in data bases. It is an integrated solution to many problems associated with all of the forgoing alternatives. The system is simpler, more flexible, more comprehensive and less difficult to implement than any other methods of the past and present.

Basically, this invention consists of a portable hand-held device incorporating a small computer with a read-out screen, equipped with (or interfacing with) a barcode scanner, plus software enabling it to interact with and manipulate data in various ways (for instance, to create data bases, to accept new data into existing data-bases, to compare data bases, and to edit them).

Portability and interactivity

The device can display its information in human readable form, as well as having a keypad for data entry by hand. Since a person can interact directly with the device without the necessity of docking with a computer at home, the device makes itself useful in ways that are beyond anything presently available.

The intent is to take maximum advantage of the portability of powerful yet small digital data devices, to provide humans with the memory aids they need when and where they most need them. While a user is away from home, with this invention, data can be acquired via barcode reader and comparisons run with data in storage. The results can be viewed immediately. This gives users an unprecedented mnemonic assistance while shopping.

Personal Shopping Assistance

Inventories stored in the hand-held device, with or without additional programming from catalogue databases, can be used in stores for facilitating purchase decisions as well as recording new additions. Pre-programmed with all previous purchases of similar items, the invention can tell its owner whether or not an item contemplated for purchase would be a duplication, upon either manual entry of numerical data or scanning of the item's bar-code.

By pre-loading the device with a database of product information, such as a book catalogue in digital form, or a portion thereof, a personal "wish list" can be stored as a memory aid while shopping. New items could be added to the wish list by entering product codes of items deemed desirable.

Digital data could be downloaded from the internet from web sites of the many companies desiring to make it convenient for people to buy their products.

The portable hand-held device can make use of existing technology to dock with a personal computer to exchange information, both to upload files for storage onto the computer or to acquire new data, as well as taking advantage of other functions of a desktop computer, such as printing capability.

The Simplest Embodiments

In one embodiment of the invention, the entire device is housed in one unit. This maximizes integration, and makes for cost-effective manufacturing, so that it maximizes value. This all-in-one approach also serves the consumer by minimizing the clutter and confusion that come from having to integrate software and hardware from several different companies on their own. The simplest embodiments smooth the way for easy use, as, at present, it takes a lot of technical know-how to rig up the components and find or write software to achieve anything near the functionality of this invention. By packaging it all together, the problem of shared responsibility is eliminated, so that if something goes wrong, instead of wondering which unit in a chain has failed or caused the problem, there is just one supplier to go to for support.

The simplicity and ease of use of the least complicated embodiments make such systems attractive to even the minimally technically astute; a tool that a great number of people can make use of.

The scope of the invention includes very task-specific embodiments, such as units that are factory configured to include a particular database, such as a “best hits” list of music titles, or a database of mystery books, for those who value simplicity, ease of use, and who don’t need more features or capacities.

It may be desirable to make use of the various types of removable memory (either as the “Smart Card” type solid state memory, or disc based) in order to give added flexibility and functionality to the simplest devices. That way, the removable memory could be replaced by one with a more up-to-date data base, or a completely different one.

More Extensive Embodiments

The more extensive embodiments would be of use to people who have more varied collections, who wanted to catalogue a number of separate sets of data, for whom flexibility would be worth some additional cost. The simplest embodiments trade extended features and utility for ease of use and cost effectiveness. People comfortable with computers will want the capability to take full advantage of the capabilities conferred by the ability to communicate with their own stored data bases and with all of the information available via the internet, as well as their own computer’s other functions. Many of those people will be happy to have the extra functionality of the embodiments that include digital communications. This is easily achieved via existing technologies such as a “cradle” or docking station which is physically attached to the desktop computer, or via wireless means.

Insurance Applications

This invention makes it easy to assemble an accurate inventory and to keep it up to date. Inventories can facilitate record keeping for insurance purposes.

As previously noted, many households have large collections of entertainment media (for example, CDs, videotapes, VideoDiscs, books), and other items too numerous to keep track of easily via the methods currently in use.

Insurance companies can be apprised of household contents via a list that is not only very detailed, but is brought up to date frequently by individuals as they add new acquisitions to the data base of “currently owned” items. The documentation can be as effortless as scanning in a bar code, so in the case of an insurance loss it is far likelier that this means of inventory-keeping will be accurate, detailed, and up to date than with any current systems.

BRIEF DESCRIPTION OF THE DRAWINGS

Other objects and advantages of the present invention will be apparent from the following detailed description of the presently preferred embodiments thereof, which description should be considered in conjunction with the accompanying drawings in which:

FIG. 1 is an exemplary simplified illustration showing one possible package for a self-contained embodiment of the present invention;

FIG. 2 is a block diagram showing the elements comprising the embodiment depicted in FIG. 1;

FIG. 3 is a block diagram showing the elements necessary for an embodiment equipped to communicate with other devices.

FIG. 4 is a block diagram showing an embodiment similar to Fig. 3 but utilizing an outboard barcode reader.

FIG. 5 is an exemplary illustration of an embodiment utilizing existing PDA hardware.

FIG. 6 is a flow diagram exemplifying software that could be used to give a personal inventory management system its basic functionality.

FIG. 7 is a more detailed flow diagram exemplifying software subroutines.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

Preferred embodiments of the present invention will be explained with reference to the accompanying drawings.

As shown in FIG. 1 and FIG. 2, a personal inventory management system of the present invention can be embodied all in one portable hand-held device 48. This simplest of embodiments must have a means for manual data entry, such as a touchscreen 26 or other means such as a keypad, a display 24, an integral barcode reader 14, at least one built-in database, and digital data storing and processing capacity.

Fig. 1 shows an embodiment made as user-friendly as possible, by eliminating all nonessential features, offering the personal inventory management system in its most basic form. It can occupy dimensions as small as business-card sized by 1/4" thick, to maximize portability. The user interfaces with it via it's combined I/O interface, preferably a touchscreen, for manual data entry and to read information on its display screen. Using the power button 18 to turn the unit on, the user, can aim its barcode reader at a selected barcode, and get a signal confirming the successful reading of a barcode from indicator 12, which may be sonic or visual, accomplished either via a small LED or a micro sound-chip. Upon receiving the signal that a barcode has been successfully read, the user presses the accept button 16, telling the unit to store the information.

This embodiment is a device independent of any sources of input other than manual data entry and barcode scanning. Therefore, to be able to decode any set of barcodes, it must come supplied with at least one factory preset database 28. (The preset database 28 provides it with the look-up tables for reference to do the decoding.) It must have at least one dynamic database 30 as well. (The dynamic database 30 is the memory component that accepts and stores new input, which the user can edit.) It requires enough digital processing power to run its internal software 34 and communicate via its interface 10. These, and a power supply 22, are the minimum requirements for this embodiment of the invention to function. The power supply 22 for the device can be a battery, fuel cell, photovoltaic or of any other kind. More features and functionality can certainly added to this basic minimum.

It is possible that this embodiment could be coupled with entirely different functions in one device, for the convenience of users who do not wish to have a lot of clutter about them. The nature of the invention can retain its integrity even if packaged in combination with other assistants.

provide the physical platform for the software necessary to accomplish the functions of a personal inventory management system.

Many companies make Personal Data Assistants (PDAs), which are essentially miniature computers, offering a wide variety of capabilities and with differing capacities for expansion and add-on devices. These PDAs are typically equipped to interface with computers and sometimes other devices.

Figure 5 is an illustration of a typical PDA. These handheld units have combination LCD readouts/touchscreens capable of performing the necessary I/O interface 10 functions, as well as offering a number of other features. A PDA usually comes equipped with a stylus 44 for use with its touchscreen 26, and it is normal for a PDA to have programmable buttons 42 to expand the range of specialized functions it can be configured to perform..

Handspring, (Handspring, Inc. 189 Bernardo Avenue View, CA) makes a PDA which has a dock 36 in the form of a slot on the back to accommodate different devices according to the owner's desires. Other companies make devices to fit into these docking slots 36. One such company, Symbol Technologies (Holtzville, New York), markets a barcode reader module 38 which docks with Handspring PDAs. With those two devices, the only necessary addition to achieve the functionality of the present invention is the addition of software and databases.

Fig. 6 and Fig 7 exemplify schematically the type of software programs that could be implemented in combination with a PDA and a barcode reader to achieve functionality as an embodiment of the invention. This software would be well within the capability of a competent programmer to write.

Elements in a development environment which could implement the software include, for example, Microsoft Windows 2000, CodeWarrior for the Palm OS, Palm OS Emulator for Windows, Palm OS Conduit Development Kit, Java for Windows, and Symbol Technology Inc.'s SPT SDK Utility Software.

Existing software which is already in use for inventory management, for PDA applications, for applications involving utilization of barcode scanners, and for creating catalogues and other kinds of manageable databases could be adapted to meet the needs of the present invention. For instance, Readerware (P.O. Box 12325, San Francisco, CA 94112-0325) makes software that would be particularly suited to easy adaptation for the purposes of this invention.

The scope of this invention is certainly not limited to the above embodiments. There is a logical adaptation to tie the technology in this system with other systems, particularly ones designed for shopping, and more specifically, for interacting over the internet.

While certain novel features of this invention have been shown and described and are pointed out in the annexed claims, it is not intended to be limited to the details above, since it will be understood that various omissions, modifications, substitutions and changes in the forms and details of the device illustrated and in its operation can be made by those skilled in the art without departing in any way from the spirit of the present invention.
